**Fact sheet compiled by** Alexis Lécu, DVM, Paris Zoo 53 avenue de St Maurice 75012 PARIS FRANCE

**Last update** March 2004

**Fact sheet reviewed by** Francis Vercammen, Royal Zoological Society, Antwerp, Belgium

**Susceptible animal groups**
All mammals are potentially susceptible. More largely spread on ruminants. Other species where infection was observed include: horse, swine, carnivores, mouse, guinea pig, rabbit, man.

**Causative organism**
*Chlamydyphila abortus*, previously named *Chlamydia psittaci* serotype 1

**Zoonotic potential**
Disease in man is of two types:
- In non-pregnant humans, infection may cause respiratory disease, but main first signs are malaise, flu-like signs, mild dry cough, dyspnoea.
- In pregnant woman, infection leads to abortion with sever complications sometimes fatal. Pregnant women should be kept away from aborting females.

**Distribution**
Enzootic world-wide. In UK, 8.6% of the flocks of sheep are estimated to be infected.

**Transmission**
Mainly aborted foetuses, placenta, vaginal discharges and infected faeces. The excretion is at its highest at the time of kidding/abortion. However, the bacteria are carried in the intestine and in some lymphoid tissue, creating carrier animals. (e.g, about 20% of sheep which have had chlamydial disease remain infective)

**Incubation period**
The colonisation of placenta happens several days before mid-pregnancy, but visible signs appear only few weeks after.

**Clinical symptoms**
- Females: Abortion sometimes associated with retained placenta, uterine discharge. Further sterility may occur. Abortion normally happens in the last half of pregnancy.
- Males: seminal vesiculitis (leading to atrophic testes)
- Rare: cough, keratoconjunctivitis, arthritis, encephalitis in calves

**Post mortem findings**
- Foetus: Congested and swollen liver, with pinpoint white foci, enlarged lymph nodes, petechiae in thymus, skin, salivary glands. When abortion occurs near the term, foetus are usually cell preserved and clean in appearance.
- Placenta:
EAZWV Transmissible Disease Fact Sheet

Diagnosis
• Histology (stains) on placenta, foetal tissues
• IFI, ELISA on placenta, foetal tissue: cross reaction with other bacteria
• PCR is the best for tissue infection diagnosis
• Serology: ELISA test, screening for unequivocal C.abortus antibody
• Egg inoculation (live cell culture): only on good quality fresh samples, 20-30 days min. culture

Material required for laboratory analysis
Histology: placenta (cotyledons), foetal liver, lung, kidney, spleen
PCR: foetal liver, lung, kidney, gastric content, urine, spleen
Live cell culture: Placenta, foetus liver, uterine discharge

Treatment
Tetracyclines could help to prevent abortion, but do not clean the issued calf, which can become a carrier.
20 mg/kg of oxytetracycline at mid pregnancy + 15 days before the birth

Prevention and control in zoos
1) Isolation of aborting dam, because excretion mainly occurs during abortion/kidding, via placental envelopes, uterine fluids, stools and milk.
2) Vaccination: killed vaccines reduce abortion, but does not reduce excretion. Live vaccine prevents excretion. It’s recommended to continue vaccination in an infected herd, as long as latent infected animals remain.
3) Pest control (transmission could occur through stools from rodents and birds)

Suggested disinfectant for housing facilities
Very resistant to cold above 0°C. Not sensible to heat. Hardly survive at –20°C, better at –80°C
Susceptible to quaternary ammoniums.
Special care of house and litter is required around kidding time

Notification

Guarantees required under EU Legislation

Guarantees required by EAZA Zoos

Measures required under the Animal Disease Surveillance Plan

Measures required for introducing animals from non-approved sources

Measures to be taken in case of disease outbreak or positive laboratory findings

Conditions for restoring disease-free status after an outbreak
